DECLARATION

I now declare that I have completed my Online Summer Training Course on Application Development in JAVA at Lovely Professional University from June 05, 2024, to July 05, 2024, under the guidance of the Human Resource Development Center. I declare that I have worked with full dedication during these 65 hours of training, and my learning outcomes fulfill the requirements for the course.

Date: 25 July 2024

Name of Student: Adarsh

Registration No: 12211442

Acknowledgement

I would like to express my sincere gratitude to Lovely Professional University for allowing me to participate in the Online Summer Training Course on Application Development in JAVA. This course, conducted from June 05, 2024, to July 05, 2024, has been a significant learning experience, helping me deepen my understanding of Java programming and application development. I am truly thankful to the Human Resource Development centre and all the faculty involved for their commitment to offering such a valuable program.

I am particularly grateful to my trainer, and the Program Coordinator, for their dedicated guidance and support throughout this training. Their constructive feedback and encouragement have greatly contributed to my learning and performance, culminating in achieving an "A" grade for this course.

Additionally, I would like to extend my thanks to my peers who participated alongside me in this course. Their camaraderie and willingness to collaborate enriched and supported the learning environment.

I also wish to acknowledge the invaluable support from my family and friends, who have been a constant source of encouragement during this training period.

Finally, I would like to express my heartfelt thanks to everyone who has helped me directly or indirectly in this journey of learning. Your contributions have been instrumental in my successful completion of the course.

Certificate

HUMAN RESOURCE DEVELOPMENT CENTER

NAAC A++

Certificate No. 340015

Certificate of Participation

This is to certify that **Mr. Adarsh** S/o Sh. Shailendra Thakur participated in **Online Summer Training Course on Application Development in JAVA** organized by Lovely Professional University w.e.f. **June 05, 2024** to **July 05, 2024** (65 Hours) and obtained **"A"** Grade.

Date of Issue : 25-07-2024	**Prepared by**	**Checked By**	**Head**
Place : Phagwara (Punjab), India	**(Administrative Officer-Records)**	**Program Coordinator**	**Human Resource Development Center**

Note: The Grades reflected are based on the performance of the participant at the time of training and performance is subject to change subsequently.

Grade Description:

O : 90% and above
A : 75% to less than 90%
B : 60% to less than 75 %
C : 50% to less than 60%
D : Below 50%

Introduction to Java Programming

An "Introduction to Java Programming" module in a Java application development course is designed to provide beginners with a solid foundation in Java, one of the most widely used programming languages for building applications. Here's an overview of what such an introduction might cover:

1. Understanding Java and Its Applications

- **History and Evolution**: A brief history of Java, including its development by Sun Microsystems (now owned by Oracle) and its evolution over the years.
- **Platform Independence**: Explanation of Java's "write once, run anywhere" (WORA) philosophy due to its platform-independent nature through the Java Virtual Machine (JVM).
- **Common Uses**: Overview of where Java is used, such as web applications, mobile applications (especially Android), desktop applications, enterprise applications, and embedded systems.

2. Setting Up the Development Environment

- **Java Development Kit (JDK)**: Instructions on how to download and install the JDK, which includes the Java compiler and runtime environment.
- **Integrated Development Environments (IDEs)**: Introduction to popular IDEs for Java development like Eclipse, IntelliJ IDEA, and NetBeans, and how to set up a basic project.

3. Basic Syntax and Structure

- **Java Program Structure**: Explanation of the basic structure of a Java program, including the class keyword, the main method, and the use of curly braces.
- **Basic Data Types**: Overview of Java's primitive data types (int, char, double, boolean, etc.) and how they are used in variables.
- **Operators**: Introduction to Java's arithmetic, relational, and logical operators.

4. Control Flow Statements

- **Conditional Statements**: Explanation of if, else if, and else statements.
- **Loops**: Introduction to looping structures like for, while, and do-while loops.
- **Switch Case**: Overview of the switch statement for multiple conditional branches.

5. Introduction to Object-Oriented Programming (OOP)

- **OOP Concepts**: Basic concepts of OOP such as classes, objects, inheritance, polymorphism, encapsulation, and abstraction.
- **Creating Classes and Objects**: How to define a class and create objects in Java.
- **Methods**: Introduction to methods (functions) in Java, including method declaration, calling, and passing arguments.

6. Error Handling

- **Exceptions**: Introduction to Java's exception handling mechanism using try, catch, finally, throw, and throws.
- **Common Exceptions**: Overview of common exceptions in Java, such as NullPointerException, ArrayIndexOutOfBoundsException, and ClassCastException.

7. Basic Input and Output

- **Using the Scanner Class**: How to take user input from the console using the Scanner class.
- **Basic File I/O**: Introduction to reading from and writing to files using Java's I/O streams.

8. Arrays and Strings

- **Arrays**: Understanding single-dimensional and multi-dimensional arrays, array manipulation, and common operations.
- **Strings**: Introduction to the String class, common string methods, and string manipulation techniques.

9. Conclusion and Next Steps

- **Recap of Learned Concepts**: Summarizing what has been covered in the introduction module.
- **Path Forward**: A brief overview of more advanced topics to be covered in later modules, such as advanced OOP concepts, data structures, GUI development, and working with databases.

This introductory module aims to equip learners with the basic knowledge and skills needed to start writing simple Java programs and prepare them for more advanced topics in Java application development.

Java Basics

In this summer training course is typically designed to introduce students to the fundamental concepts of Java programming. This module builds a solid foundation for learners who are new to programming or new to Java, providing them with the essential skills to understand and write basic Java code. Here's an overview of what "Java Basics" might include:

1. Introduction to Java

- **Overview of Java**: Explanation of what Java is, its history, and why it is a popular programming language.
- **Features of Java**: Discuss key features such as simplicity, object-oriented, platform independence, robustness, security, multithreading, and portability.

2. Setting Up the Development Environment

- **Installing Java Development Kit (JDK)**: Step-by-step guide on installing the JDK on different operating systems (Windows, macOS, Linux).
- **Configuring the IDE**: Setting up an Integrated Development Environment (IDE) like Eclipse, IntelliJ IDEA, or NetBeans to write and run Java programs.

3. Basic Syntax and Structure of a Java Program

- **Hello World Program**: Writing the first simple Java program to display "Hello, World!" on the console. Explanation of the structure of a basic Java program, including the class keyword, main method, and the use of braces {}.
- **Java Identifiers and Keywords**: Overview of valid identifiers in Java (rules for naming variables, methods, etc.) and reserved keywords that cannot be used as identifiers.

4. Data Types and Variables

- **Primitive Data Types**: Introduction to Java's primitive data types (int, char, float, double, boolean, byte, short, long) and their uses.
- **Declaring and Initializing Variables**: How to declare and initialize variables of different data types.
- **Type Casting**: Explanation of implicit and explicit type casting in Java

5. Operators in Java

- **Arithmetic Operators**: Introduction to arithmetic operators (+, -, *, /, %) for performing mathematical operations.
- **Relational Operators**: Discuss relational operators (==, !=, >, <, >=, <=) for comparing values.
- **Logical Operators**: Overview of logical operators (&&, ||, !) used in conditional statements.
- **Assignment Operators**: Explanation of assignment operators (=, +=, -=, *=, /=, %=) and their shorthand versions.

6. Control Flow Statements

- **Conditional Statements**: Explanation of if, else if, and else statements for decision-making.
- **Switch Statement**: Introduction to the switch statement for handling multiple possible values of a variable.
- **Loops**: Explanation of loops (for, while, do-while) to execute a block of code multiple times.
- **Break and Continue Statements**: Discuss the use of break to exit a loop and continue to skip the current iteration.

7. Arrays

- **Introduction to Arrays**: Understanding arrays as a collection of data items of the same type.
- **Declaring, Initializing, and Accessing Arrays**: How to create and manipulate single-dimensional arrays.
- **Multidimensional Arrays**: Brief overview of two-dimensional arrays and how to use them.

8. Strings in Java

- **Introduction to Strings**: Understanding strings as objects in Java and how they differ from primitive data types.
- **Common String Methods**: Overview of commonly used string methods (e.g., length(), charAt(), substring(), indexOf(), concat()).

9. Basic Input and Output

- **Using the Scanner Class**: How to read user input from the console using the Scanner class.
- **Basic Output**: Using System.out.print() and System.out.println() for displaying output on the console.

10. Introduction to Methods

- **Defining and Calling Methods**: How to create methods to perform specific tasks and how to call them.
- **Method Parameters and Return Types**: Understanding how to pass data to methods and how methods can return data.

11. Basic Exception Handling

- **Introduction to Exceptions**: Understanding what exceptions are and how they affect program execution.
- **Try-Catch Blocks**: Basic use of try and catch blocks to handle exceptions and ensure smooth program flow.

12. Basic Object-Oriented Concepts

- **Introduction to Classes and Objects**: Basic understanding of objects, classes, and the concept of object-oriented programming (OOP).
- **Simple Class Creation**: Creating a simple class with attributes (fields) and methods.

13. Conclusion and Practice

- **Recap of Learned Concepts**: Summarizing all the basic concepts covered in this module.
- **Hands-on Practice**: Encouragement to practice by writing small programs and solving exercises to reinforce learning.

This "Java Basics" module is essential for laying the groundwork for more advanced topics in Java, such as data structures, algorithms, and application development. It ensures that learners have a strong understanding of the fundamental concepts and are prepared to move on to more complex programming challenges.

Object-Oriented Programming (OOP) in Java

Object-Oriented Programming (OOP) in Java is a programming paradigm that organizes software design around data, or objects, rather than functions and logic. It allows developers to create modular, reusable, and maintainable code. Here are the core concepts of OOP in Java:

1. Classes and Objects

- **Class**: A blueprint for creating objects. It defines a data type by bundling data (attributes) and methods (functions) that operate on the data.
- **Object**: An instance of a class. Objects are created based on the class and can have different values for their attributes.

2. Encapsulation

- Encapsulation is the practice of hiding the internal state and behavior of an object and only exposing a controlled interface. This is achieved using access modifiers (private, protected, public), which control the visibility of class members.

3. Inheritance

- Inheritance allows a new class (subclass or child class) to inherit fields and methods from an existing class (superclass or parent class). This promotes code reuse and establishes a hierarchical relationship between classes.

4. Polymorphism

- Polymorphism allows objects to be treated as instances of their parent class rather than their actual class. There are two types:
    - **Compile-time polymorphism (Method Overloading)**: Multiple methods in the same class with the same name but different parameters.
    - **Runtime polymorphism (Method Overriding)**: A subclass provides a specific implementation of a method that is already defined in its superclass.

5. Abstraction

- Abstraction is the concept of hiding complex implementation details and showing only the necessary features of an object. In Java, abstraction is achieved using abstract classes and interfaces.

6. Interfaces and Abstract Classes

- **Interface**: A reference type in Java, similar to a class, but it can contain only abstract methods (methods without a body) and final fields (constants). A class implements an interface to provide the method bodies.
- **Abstract Class**: A class that cannot be instantiated and may contain abstract methods, which are declared without an implementation.

These principles of OOP help in creating flexible, scalable, and easy-to-maintain software systems. By leveraging classes and objects, developers can model real-world entities and relationships in their applications.

Exception Handling

Exception handling in Java is a mechanism that allows developers to manage and respond to errors or unexpected events that occur during the execution of a program. It helps maintain the normal flow of the application even when errors occur, ensuring the program doesn't crash and handles errors gracefully.

Key Concepts of Exception Handling in Java

1. **Exception**: An exception is an event that disrupts the normal flow of a program. It is an object that represents an error or an unexpected event. In Java, exceptions are of two main types:
    - **Checked Exceptions**: Exceptions that are checked at compile-time. They must be either caught or declared in the method signature using the throws keyword. Examples include IOException, SQLException, etc.
    - **Unchecked Exceptions**: Exceptions that occur at runtime and are not checked at compile-time. These are usually programming bugs, such as logic errors or improper use of an API. Examples include NullPointerException, ArrayIndexOutOfBoundsException, ArithmeticException, etc.
2. **Exception Hierarchy**: In Java, all exceptions are subclasses of the Throwable class. The Throwable class has two main subclasses:
    - **Exception**: Represents errors that a typical application might want to catch.
    - **Error**: Represents serious problems that a reasonable application should not try to catch, like OutOfMemoryError, StackOverflowError, etc.
3. **Try-Catch Block**: This is the primary mechanism for handling exceptions.
    - **try block**: Code that might throw an exception is placed inside a try block.
    - **catch block**: Used to handle the exception. It catches exceptions thrown by the try block and executes the code inside it. You can have multiple catch blocks to handle different types of exceptions.

-
- **Syntax**:

java

Copy code

```
try {

} catch (ExceptionType1 e1) {

} catch (ExceptionType2 e2) {

}
```

4. **Finally Block**: The finally block is used to execute important code such as closing resources, regardless of whether an exception is thrown or not. It always executes after the try and catch blocks.
    - **Syntax**:

java

Copy code

```
try {
   // Code that may throw an exception
} catch (ExceptionType e) {
   // Code to handle exception
} finally {
   // Code that will always execute
}
```

5. **Throwing Exceptions**: The throw keyword is used to explicitly throw an exception. This can be used for custom error handling or when a specific condition occurs that prevents further execution.
    - **Syntax**:

java

Copy code

```
throw new ExceptionType("Error message")
```

6 **Throws Keyword**: Used in the method signature to indicate that a method may throw one or more exceptions. This is typically used for checked exceptions to inform the calling method that it should handle or declare the exception.

- **Syntax**:

java

Copy code

```
public void myMethod() throws IOException, SQLException {
    // Code that may throw IOException or SQLException
}
```

Example of Exception Handling in Java

Here's a simple example that demonstrates exception handling using a try-catch block:

java

Copy code

```
public class ExceptionHandlingExample {
    public static void main(String[] args) {
        try {
            int[] numbers = {1, 2, 3};
            System.out.println(numbers[3]);  // This line will throw
ArrayIndexOutOfBoundsException
        } catch (ArrayIndexOutOfBoundsException e) {
            System.out.println("Array index is out of bounds! Please check the index.");
        } finally {
            System.out.println("This is the finally block, and it always executes.");
        }
    }
}
```

Output:

csharp

Copy code

Array index is out of bounds! Please check the index.

This is the finally block, and it always executes.

Benefits of Exception Handling

- **Robustness**: Helps in writing robust code that can handle unexpected situations without crashing.
- **Readability**: Separates error-handling code from regular code, making programs easier to read and maintain.
- **Controlled Handling**: Provides a controlled mechanism to handle exceptions, allowing the program to take appropriate actions or recover from errors.

Exception handling is a crucial aspect of Java programming, enabling developers to write error-resistant and maintainable code.

Collections Framework

The Java Collections Framework is a set of classes and interfaces that implement commonly reusable collection data structures. These collections provide a way to store and manipulate groups of objects in a consistent and efficient manner. Here's a brief overview of the key components of the Java Collections Framework:

1. Core Interfaces

The framework is built around several core interfaces, each defining a specific type of collection:

- **Collection<E>**: The root interface of the collection hierarchy. It represents a group of objects, known as elements.
- **List<E>**: An ordered collection (also known as a sequence). Lists can contain duplicate elements and allow positional access.
  - **Implementations**: ArrayList, LinkedList, Vector, Stack.
- **Set<E>**: A collection that does not allow duplicate elements. It models the mathematical set abstraction.
  - **Implementations**: HashSet, LinkedHashSet, TreeSet.
- **Queue<E>**: A collection designed for holding elements prior to processing. Typically, queues are used for FIFO (first-in, first-out) order.
  - **Implementations**: LinkedList, PriorityQueue, ArrayDeque.
- **Deque<E>**: A double-ended queue that supports element insertion and removal at both ends.
  - **Implementations**: ArrayDeque, LinkedList.
- **Map<K, V>**: An object that maps keys to values. A map cannot contain duplicate keys; each key can map to at most one value.
  - **Implementations**: HashMap, LinkedHashMap, TreeMap, Hashtable.

2. Key Classes

- **ArrayList**: A resizable array implementation of the List interface. Provides fast random access to elements but slower insertions and deletions.
- **LinkedList**: A doubly-linked list implementation of the List and Deque interfaces. Provides better performance for insertions and deletions.
- **HashSet**: An implementation of the Set interface backed by a hash table. It does not maintain any order for elements.
- **TreeSet**: A Set implementation that maintains elements in ascending order, based on their natural ordering or a provided comparator.
- **HashMap**: A Map implementation based on a hash table. Provides fast access to elements but does not maintain any order.
- **TreeMap**: A Map implementation that maintains elements in ascending key order, based on their natural ordering or a provided comparator.

3. Utility Class

- **Collections**: A utility class that consists of static methods to operate on or return collections. It includes methods for sorting, searching, and reversing lists, among other utilities.

4. Generics

The Java Collections Framework uses generics to ensure type safety. This allows collections to be parameterized with a specific type, eliminating the need for casting and preventing ClassCastException at runtime.

5. Benefits of the Collections Framework

- **Unified Architecture**: Provides a standard way to handle groups of objects.
- **Reduce Programming Effort**: Comes with a rich set of data structures and algorithms ready for use.
- **Increased Performance**: Optimized for performance with specific use cases in mind.
- **Ease of Learning**: Unified interfaces reduce the learning curve for new developers.

Example Usage

Here's a simple example that demonstrates some of the common classes in the Collections Framework:

```
import java.util.*;
```

```
public class CollectionsExample {
    public static void main(String[] args) {
        List<String> list = new ArrayList<>();
        list.add("Apple");
        list.add("Banana");
        list.add("Cherry");
        System.out.println("List: " + list);
        Set<String> set = new HashSet<>();
        set.add("Apple");
        set.add("Banana");
        set.add("Apple");  // Duplicate element, will not be added
        System.out.println("Set: " + set);
        Map<String, Integer> map = new HashMap<>();
        map.put("Apple", 1);
        map.put("Banana", 2);
        map.put("Cherry", 3);
        System.out.println("Map: " + map);
    }
}
```

Output:

List: [Apple, Banana, Cherry]

Set: [Apple, Banana]

Map: {Apple=1, Banana=2, Cherry=3}

The Java Collections Framework provides a robust foundation for handling data structures and is essential for any Java developer to master for efficient and effective programming.

File Handling in Java

File handling in Java involves reading from and writing to files on the file system using various classes provided in the java.io and java.nio.file packages. Here's a quick overview:

Key Classes for File Handling

1. **File**: Represents a file or directory path. It provides methods to create, delete, and get information about files and directories.
2. **FileReader and FileWriter**: Used for reading and writing text files (character based I/O).
3. **BufferedReader and BufferedWriter**: Provide efficient reading and writing by buffering input and output. These classes are used for handling large files efficiently.
4. **FileInputStream and FileOutputStream**: Used for reading and writing binary data (byte based I/O).
5. **Files** (from java.nio.file package): Provides utility methods for file operations like copying, moving, deleting, and reading all lines from a file.

Basic File Operations

- **Creating a File**: Use the File class with createNewFile() to create a new file.
- **Writing to a File**: Use FileWriter or BufferedWriter for writing text data, and FileOutputStream for writing binary data.
- **Reading from a File**: Use FileReader or BufferedReader for reading text data, and FileInputStream for reading binary data.
- **Deleting a File**: Use the delete() method from the File class.

Example: Writing and Reading Text

```
import java.io.*;

public class FileHandlingExample {

    public static void main(String[] args) {

        // Writing to a file

        try (BufferedWriter writer = new BufferedWriter(new FileWriter("example.txt"))) {

            writer.write("Hello, world!");

        } catch (IOException e) {
```

```
            e.printStackTrace();
        }

        // Reading from a file
        try (BufferedReader reader = new BufferedReader(new FileReader("example.txt")))
{
            String line;
            while ((line = reader.readLine()) != null) {
                System.out.println(line);
            }
        } catch (IOException e) {
            e.printStackTrace();
        }
    }
}
```

Summary

Java provides robust support for file handling, allowing you to efficiently manage file operations using various classes and methods tailored for different data types and purposes.

Java Streams and Lambda Expressions

Java Streams and Lambda Expressions, introduced in Java 8, provide powerful ways to process data and implement functional programming paradigms. Here's a brief overview:

Java Streams

Streams are a part of the java.util.stream package and represent a sequence of elements that can be processed in a pipeline. Streams allow for functional-style operations on collections and other data sources, enabling concise and readable code.

Key Features:

- **Declarative Processing**: Streams allow for declarative code where you express what to do rather than how to do it.
- **Pipeline Operations**: Stream operations are chained together in a pipeline, consisting of a source (e.g., collection), zero or more intermediate operations (e.g., filter, map), and a terminal operation (e.g., forEach, collect).
- **Lazy Evaluation**: Intermediate operations are lazy; they are not executed until a terminal operation is invoked, optimizing performance.
- **Parallel Processing**: Streams can easily be converted to parallel streams for concurrent execution using parallelStream(), which can improve performance on multi-core processors.

Example:

```
import java.util.Arrays;

import java.util.List;

public class StreamExample {

    public static void main(String[] args) {

        List<String> names = Arrays.asList("Alice", "Bob", "Charlie", "David");

        names.stream()

            .filter(name -> name.startsWith("C"))

            .forEach(System.out::println); // Output: Charlie

    }

}
```

Lambda Expressions

Lambda expressions are a way to represent anonymous functions (methods without a name) and provide a clear and concise syntax to write inline implementations of functional interfaces (interfaces with a single abstract method).

Key Features:

- **Conciseness**: Reduces boilerplate code by eliminating the need for anonymous class implementations.
- **Functional Interface Compatibility**: Lambdas can be used wherever a functional interface is expected, making them versatile.
- **Readable Syntax**: Simplifies code by using a clear syntax for simple method implementations.

Syntax:

```
(parameters) -> { expression or statements }
```

Example:

```
import java.util.Arrays;

import java.util.List;

public class LambdaExample {

    public static void main(String[] args) {

        List<Integer> numbers = Arrays.asList(1, 2, 3, 4, 5);

        numbers.forEach(n -> System.out.println(n));

    }

}
```

Summary

- **Java Streams** enable functional-style operations on sequences of elements, providing a powerful tool for processing collections and data.
- **Lambda Expressions** simplify the syntax for implementing functional interfaces, making the code more concise and readable. Together, they allow for more expressive and functional programming in Java

Multithreading and Concurrency

Multithreading and **Concurrency** in Java refer to the ability of a program to perform multiple tasks simultaneously and manage the execution of threads. Here's a concise overview:

Multithreading

- **Definition**: Multithreading allows a program to execute multiple threads concurrently within the same process, improving efficiency and responsiveness.
- **Threads**: The smallest unit of execution. Each thread runs independently but shares resources (e.g., memory) with other threads in the same process.
- **Creating Threads**: You can create threads by extending the Thread class or implementing the Runnable interface and passing it to a Thread object.

Example:

```
public class MyThread extends Thread {
    public void run() {
        System.out.println("Thread is running");
    }
}
public class Main {
    public static void main(String[] args) {
        MyThread thread = new MyThread();
        thread.start(); // Starts the thread
    }
}
```

Concurrency

- **Definition**: Concurrency refers to managing multiple threads running simultaneously, including their interaction and synchronization.
- **Synchronization**: Mechanisms like synchronized blocks or methods, and higher-level concurrency utilities (e.g., ExecutorService, CountDownLatch) are used to control access to shared resources and avoid issues like race conditions

Java GUI Development

Java GUI (Graphical User Interface) development involves creating graphical interfaces for Java applications. Java provides several libraries and frameworks for building GUIs. Here's a concise overview:

Key Libraries and Frameworks

1. **AWT (Abstract Window Toolkit)**
   - **Overview**: The original Java GUI library.
   - **Components**: Provides basic components like buttons, text fields, and windows.
   - **Limitations**: Limited flexibility and features compared to Swing and JavaFX.
2. **Swing**
   - **Overview**: An extension of AWT that provides a richer set of GUI components.
   - **Components**: Includes components like JButton, JLabel, JPanel, JTable, and more.
   - **Features**: Better look-and-feel customization and lightweight components.

Example:

```
import javax.swing.*;

public class SwingExample {

    public static void main(String[] args) {

        JFrame frame = new JFrame("Swing Example");

        JButton button = new JButton("Click Me");

        frame.getContentPane().add(button);

        frame.setSize(300, 200);

        frame.setDefaultCloseOperation(JFrame.EXIT_ON_CLOSE);

        frame.setVisible(true);

    }

}
```

3. **JavaFX**

- **Overview**: A modern GUI toolkit that provides a more advanced set of features than Swing.
- **Components**: Includes controls like Button, TextField, TableView, and layout managers.
- **Features**: Supports rich UI features like animations, 3D graphics, and CSS styling.

Example:

```
import javafx.application.Application;
import javafx.scene.Scene;
import javafx.scene.control.Button;
import javafx.scene.layout.VBox;
import javafx.stage.Stage;
public class JavaFXExample extends Application {
    @Override
    public void start(Stage primaryStage) {
        Button button = new Button("Click Me");
        VBox root = new VBox(button);
        Scene scene = new Scene(root, 300, 200);
        primaryStage.setScene(scene);
        primaryStage.setTitle("JavaFX Example");
        primaryStage.show();  }
    public static void main(String[] args) {
        launch(args);  }
}
```

Summary

- **AWT**: Basic GUI components, older and less flexible.
- **Swing**: Enhanced GUI components and customization options, still widely used.
- **JavaFX**: Modern, feature-rich toolkit for creating sophisticated and visually appealing UIs.

Database Connectivity

Database connectivity in Java allows applications to interact with databases for operations like querying, updating, and managing data. This is typically done using JDBC (Java Database Connectivity). Here's a brief overview:

Key Components

1. **JDBC (Java Database Connectivity)**
    - **Overview**: A standard API for connecting and executing queries with relational databases.
    - **Driver**: A set of classes that handle the connection between Java applications and a specific database. Different databases require different drivers (e.g., MySQL, PostgreSQL).
2. **DriverManager**
    - **Purpose**: Manages a list of database drivers. It is used to establish a connection to the database.
3. **Connection**
    - **Purpose**: Represents a connection to a specific database. It is used to create statements and manage transactions.
4. **Statement**
    - **Purpose**: Used to execute SQL queries. There are different types of statements:
        - **Statement**: For executing simple queries.
        - **PreparedStatement**: For executing precompiled SQL queries with parameters, which helps in preventing SQL injection and improving performance.
        - **CallableStatement**: For executing stored procedures.
5. **ResultSet**
    - **Purpose**: Represents the result set of a query. It allows iteration over the results and retrieval of data.
6. **SQLException**
    - **Purpose**: Handles SQL-related errors that occur during database operations.

Basic Steps for Database Connectivity

1. **Load the JDBC Driver**: Register the driver class to make it available to the application.
2. **Establish a Connection**: Use DriverManager to connect to the database with a connection string (URL), username, and password.
3. **Create a Statement**: Use the Connection object to create a Statement or PreparedStatement for executing SQL queries.
4. **Execute a Query**: Run SQL queries using the Statement object and obtain results via a ResultSet.
5. **Process the Results**: Iterate through the ResultSet to retrieve and process the query results.
6. **Close Resources**: Close the ResultSet, Statement, and Connection objects to free up database resources.

Example Code

Connecting to a MySQL Database and Querying Data:

java

Copy code

```
import java.sql.Connection;

import java.sql.DriverManager;

import java.sql.ResultSet;

import java.sql.Statement;

import java.sql.SQLException;

public class DatabaseExample {

    public static void main(String[] args) {

        String url = "jdbc:mysql://localhost:3306/mydatabase";

        String user = "root";

        String password = "password";

        try {

          Class.forName("com.mysql.cj.jdbc.Driver");
```

```
            Connection conn = DriverManager.getConnection(url, user, password);
            Statement stmt = conn.createStatement();
            ResultSet rs = stmt.executeQuery("SELECT * FROM mytable");
            while (rs.next()) {
                System.out.println("ID: " + rs.getInt("id") + ", Name: " + rs.getString("name"));
            }
            rs.close();
            stmt.close();
            conn.close();
        } catch (ClassNotFoundException | SQLException e) {
            e.printStackTrace();
        }
    }
}
```

Summary

- **JDBC**: Provides the API for connecting and interacting with databases.
- **DriverManager**: Manages JDBC drivers and establishes connections.
- **Connection, Statement, and ResultSet**: Key classes for executing queries and processing results.
- **SQLException**: Handles SQL errors.

JDBC is fundamental for database connectivity in Java, enabling applications to perform a wide range of database operations efficiently.

Java Networking

Java networking enables applications to communicate over networks using various protocols. The core classes and interfaces for networking are provided in the java.net package. Here's a brief overview:

Key Classes and Interfaces

1. **Socket**
   - **Purpose**: Represents a client-side socket that connects to a server. Used for communication between a client and a server over TCP.
   - **Example**: Socket socket = new Socket("localhost", 8080);
2. **ServerSocket**
   - **Purpose**: Represents a server-side socket that listens for incoming connections from clients. Used to establish a server that can accept connections.
   - **Example**: ServerSocket serverSocket = new ServerSocket(8080);
3. **InetAddress**
   - **Purpose**: Represents an IP address. Provides methods to obtain IP addresses and hostnames.
   - **Example**: InetAddress address = InetAddress.getByName("localhost");
4. **URL and URLConnection**
   - **Purpose**: Used for handling HTTP connections and accessing resources over the web.
   - **Example**:

URL url = new URL("http://example.com");

URLConnection connection = url.openConnection();

5. **DatagramSocket and DatagramPacket**
   - **Purpose**: Used for UDP (User Datagram Protocol) communication. DatagramSocket is for sending and receiving packets, and DatagramPacket represents the packets themselves.
   - **Example**:

```
DatagramSocket socket = new DatagramSocket();
DatagramPacket packet = new DatagramPacket(data, data.length, address, port);
socket.send(packet);
```

Basic Steps for Network Communication

1. **Client-Server Communication Using Sockets**
    - **Client**:
        - Create a Socket object to connect to the server.
        - Use input and output streams to send and receive data.
    - **Server**:
        - Create a ServerSocket object to listen for incoming connections.
        - Accept connections using accept() method and handle them with Socket objects.
2. **Example: Simple Client-Server Application**

Server Code:

```
import java.io.*;
import java.net.*;
public class Server {
    public static void main(String[] args) throws IOException {
        ServerSocket serverSocket = new ServerSocket(12345);
        System.out.println("Server is listening on port 12345");
       Socket socket = serverSocket.accept();
        System.out.println("Client connected");
       BufferedReader in = new BufferedReader(new
InputStreamReader(socket.getInputStream()));
        PrintWriter out = new PrintWriter(socket.getOutputStream(), true);
        String message = in.readLine();
        System.out.println("Received from client: " + message);
        out.println("Hello from server!");

        socket.close();
        serverSocket.close();
    }
}
```

Client Code:

```
import java.io.*;
import java.net.*;

public class Client {
    public static void main(String[] args) throws IOException {
        Socket socket = new Socket("localhost", 12345);

        PrintWriter out = new PrintWriter(socket.getOutputStream(), true);
```

```
        BufferedReader in = new BufferedReader(new
InputStreamReader(socket.getInputStream()));

        out.println("Hello from client!");
        String response = in.readLine();
        System.out.println("Received from server: " + response);

        socket.close();
    }
}
```

Summary

- **Sockets**: Used for TCP communication; Socket (client) and ServerSocket (server).
- **DatagramSocket**: Used for UDP communication.
- **URL and URLConnection**: Used for accessing web resources.
- **InetAddress**: Represents IP addresses.

Java’s networking capabilities allow for both simple and complex networked applications, from basic client-server interactions to web-based resource access.

Introduction to Spring Framework (Optional)

The Spring Framework is a powerful, versatile framework for building Java applications. It simplifies the development of complex, enterprise-level applications by providing comprehensive infrastructure support. Here's a high-level overview:

Key Features

1. **Inversion of Control (IoC)**
    - **Purpose**: Manages the lifecycle and configuration of application objects through dependency injection.
    - **Benefit**: Decouples components, making the application easier to manage and test.
2. **Dependency Injection (DI)**
    - **Purpose**: Automatically injects dependencies into beans (objects) rather than requiring manual instantiation and management.
    - **Types**: Constructor injection, setter injection, and field injection.
3. **Aspect-Oriented Programming (AOP)**
    - **Purpose**: Separates cross-cutting concerns (such as logging and security) from business logic.
    - **Benefit**: Promotes cleaner code by modularizing aspects that affect multiple parts of the application.
4. **Spring Boot**
    - **Purpose**: Simplifies the setup and development of Spring applications with built-in features.
    - **Features**: Auto-configuration, embedded servers (e.g., Tomcat), and production-ready metrics.
5. **Spring Data Access**
    - **Purpose**: Provides comprehensive support for data access and transaction management.
    - **Components**: JDBC, JPA (Java Persistence API), and ORM (Object-Relational Mapping) frameworks like Hibernate.

6. **Spring MVC**
    - **Purpose**: Facilitates the development of web applications using the Model-View-Controller pattern.
    - **Components**: Controllers, view resolvers, and model attributes for managing web requests and responses.

Basic Concepts

1. **Beans and the ApplicationContext**
    - **Beans**: Objects managed by the Spring container.
    - **ApplicationContext**: The central interface to the Spring IoC container, responsible for creating and managing beans.
2. **Configuration**
    - **XML Configuration**: Define beans and their dependencies in XML files.
    - **Java Configuration**: Use @Configuration classes and @Bean annotations to define beans.
    - **Annotation-Based Configuration**: Use annotations like @Component, @Service, @Repository, and @Controller for automatic bean detection.

Example Code

Java Configuration Example:

java

Copy code

```
import org.springframework.context.annotation.Bean;

import org.springframework.context.annotation.Configuration;

@Configuration

public class AppConfig {

    @Bean

    public MyService myService() {

        return new MyService();

    }
```

Spring Boot Application:

```
import org.springframework.boot.SpringApplication;

import org.springframework.boot.autoconfigure.SpringBootApplication;

@SpringBootApplication

public class MySpringBootApplication {

    public static void main(String[] args) {

        SpringApplication.run(MySpringBootApplication.class, args);

    }

}
```

Summary

- **Spring Framework**: Provides a comprehensive foundation for building Java applications with features like IoC, DI, and AOP.
- **Spring Boot**: Eases application setup with auto-configuration and embedded servers.
- **Spring MVC**: Facilitates web application development using a structured approach.

Spring's modular design and extensive ecosystem make it a popular choice for developing robust, scalable, and maintainable Java applications.

Project Work

Creating a calculator application can be a great project to practice programming concepts and build an application from scratch. Here’s a basic guide to building a simple calculator application in Java.

Features of the Calculator

1. **Basic Arithmetic Operations**: Addition, subtraction, multiplication, and division.
2. **User Interface**: A graphical interface with buttons for each digit and operation.
3. **Input Validation**: Handle invalid inputs and divide by zero scenarios.

Steps to Create a Calculator Application

1. Setup Your Project

If you're using an IDE like IntelliJ IDEA or Eclipse, create a new Java project. You can also set up your project manually if you prefer.

2. Create the GUI

You can use Swing to build a simple graphical user interface (GUI). Here's a basic example of a calculator using Swing.

Calculator.java

```
import javax.swing.*;

import java.awt.*;

import java.awt.event.ActionEvent;

import java.awt.event.ActionListener;

public class Calculator extends JFrame implements ActionListener {

    private JTextField display;

    private JButton[] numberButtons;

    private JButton addButton, subButton, mulButton, divButton, eqButton, clrButton;

    private JPanel panel;

    private double num1 = 0, num2 = 0;

    private char operator = '\0';

    public Calculator() {

        setTitle("Calculator");
```

```
    setSize(400, 600);
    setDefaultCloseOperation(JFrame.EXIT_ON_CLOSE);
    setLayout(new BorderLayout());
    display = new JTextField();
    display.setEditable(false);
    add(display, BorderLayout.NORTH);
    String[] buttonLabels = {
        "7", "8", "9", "C",
        "4", "5", "6", "/",
        "1", "2", "3", "*",
        "0", ".", "=", "+"
    };
    numberButtons = new JButton[10];
    panel = new JPanel();
    panel.setLayout(new GridLayout(4, 4, 10, 10));

    for (String label : buttonLabels) {
        JButton button = new JButton(label);
        button.addActionListener(this);
        panel.add(button);
    }
    add(panel, BorderLayout.CENTER);
}
@Override
public void actionPerformed(ActionEvent e) {
    String command = e.getActionCommand();
    if (command.charAt(0) >= '0' && command.charAt(0) <= '9') {
        display.setText(display.getText() + command);
```

```
} else if (command.charAt(0) == 'C') {
    display.setText("");
    num1 = num2 = 0;
    operator = '\0';
} else if (command.charAt(0) == '=') {
    num2 = Double.parseDouble(display.getText());
    switch (operator) {
        case '+':
            display.setText(String.valueOf(num1 + num2));
            break;
        case '-':
            display.setText(String.valueOf(num1 - num2));
            break;
        case '*':
            display.setText(String.valueOf(num1 * num2));
            break;
        case '/':
            if (num2 != 0) {
                display.setText(String.valueOf(num1 / num2));
            } else {
                display.setText("Error");
            }
            break;
    }
    operator = '\0';
} else {
    if (operator == '\0') {
        num1 = Double.parseDouble(display.getText());
```

```
                display.setText("");
                operator = command.charAt(0);
            }
        }
    }
public static void main(String[] args) {
        SwingUtilities.invokeLater(() -> {
            Calculator calculator = new Calculator();
            calculator.setVisible(true);
        });
    }
}
```

Key Points

1. **Swing Components**: Used for creating GUI elements such as buttons and text fields.
2. **Event Handling**: ActionListener is used to handle user interactions.
3. **Layout Management**: BorderLayout and GridLayout are used to arrange components on the screen.
4. **Basic Arithmetic Operations**: Handled using simple conditional logic and arithmetic.

Enhancements

1. **Error Handling**: Improve error handling for invalid inputs and edge cases.
2. **Advanced Operations**: Add support for more complex functions like square roots or exponents.
3. **Styling**: Customize the look and feel of the calculator with additional styling.

This simple calculator serves as a foundation. You can expand and refine it to include more features and handle more complex scenarios.

Conclusion

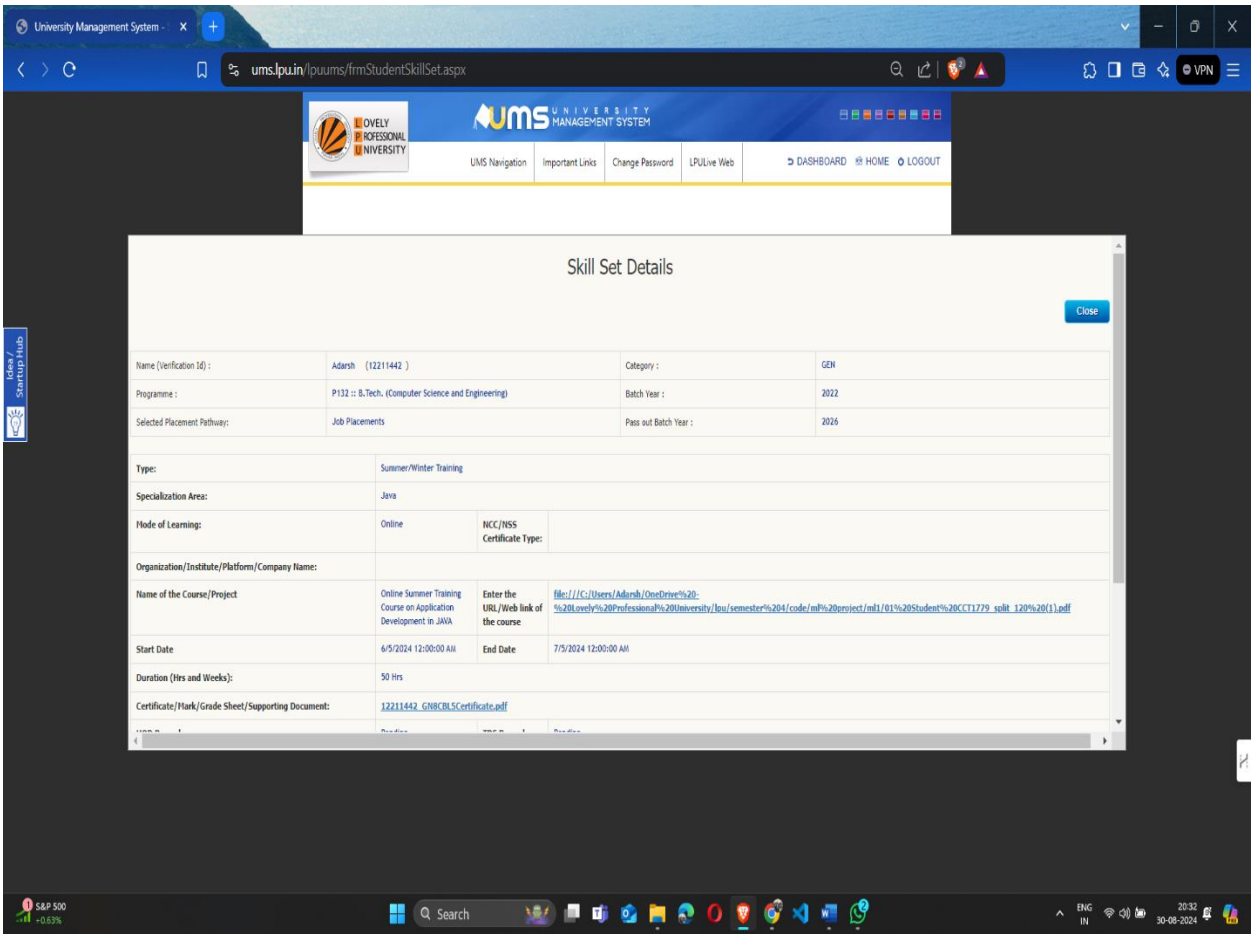
Building a calculator application is an excellent way to practice and apply fundamental programming concepts. Here's a summary of key takeaways from developing a basic calculator:

Key Concepts

1. **Graphical User Interface (GUI)**:
    - **Swing**: Java's GUI toolkit used to create the user interface components like buttons, text fields, and panels.
    - **Layout Managers**: Used to arrange components within the window (e.g., GridLayout, BorderLayout).
2. **Event Handling**:
    - **ActionListener**: An interface used to handle user actions such as button clicks.
    - **Action Commands**: Differentiates between different buttons and performs corresponding actions.
3. **Basic Arithmetic Operations**:
    - Implementing core functionalities like addition, subtraction, multiplication, and division.
    - Handling edge cases such as division by zero and input validation.
4. **Application Structure**:
    - **Class Definition**: Encapsulates the application logic within a class.
    - **Main Method**: Launches the application and initializes the GUI.

Next Steps

1. **Error Handling**:
    - Improve user experience by providing clear error messages and handling invalid inputs gracefully.
2. **Enhanced Features**:
    - Add more advanced mathematical operations and functionalities to make the calculator more versatile.

3. **User Interface Enhancements**:
    - Customize the look and feel of the application with different styles, themes, or layouts.
4. **Testing and Refinement**:
    - Test the application thoroughly to ensure it handles all scenarios and edge cases effectively.
    - Refactor the code to improve readability and maintainability.


Creating this basic calculator helps solidify foundational programming skills and provides a platform for exploring more complex applications and features.
